

Sprint 1

AI Usage Log

Course: SOEN 341 - Software Process

Project: CareerConnect - Job Search and Application Tracking Platform

Sprint: Sprint 1

Responsible Person: Elyes Jallouli

Task 1: Understanding the Resume Backend Requirements

Purpose of AI Use:

I used the AI as a learning aid to better understand the existing CareerConnect backend structure and what was expected from the resume management backend before making changes to the project.

Chat Link or Prompt/Response:

Prompt: "Help me understand the existing backend structure and how the resume management feature should fit into it."

AI-Suggested Content:

The AI explained the role of the controller, service, repository, entity, and response model layers and described how a resume request could move through the Spring Boot application. It also helped identify the main operations needed for the feature: upload, list, download, and delete.

Validation:

I inspected the existing Spring Boot package structure and compared the explanation with the patterns already used in the project. I used the existing codebase, project requirements, and team task division as the basis for deciding how my implementation should be organized.

Decision:

Accepted.

Reflection:

The AI helped me understand how the different backend layers interact. This made it easier for me to work within the existing architecture instead of treating the resume feature as a separate application.

Task 2: Understanding Local Resume Storage

Purpose of AI Use:

I used the AI to understand possible ways to store uploaded resume files and, specifically, how local file storage could work in a Spring Boot application.

Chat Link or Prompt/Response:

Prompt: "Explain how I can implement the resume backend using local file storage instead of S3."

AI-Suggested Content:

The AI explained that the uploaded file itself could be stored in a local directory while information about the resume could be stored separately in the database. It described using a unique internal filename to avoid collisions while preserving the original filename as metadata.

Validation:

I discussed the storage approach with my team. The team confirmed that AWS was not already configured and that local storage was acceptable for the project. I therefore selected the local approach rather than adding an unnecessary external dependency.

Decision:

Modified before use. I used the local-storage concept after confirming it with the team and adapted it to the existing CareerConnect backend.

Reflection:

This helped me understand the difference between file storage and database metadata. The final storage choice was based on the project context and team discussion, not solely on the AI suggestion.

Task 3: File Validation and Resume Metadata

Purpose of AI Use:

I used the AI to understand reasonable validation checks for uploaded resumes and which information should be kept in the database.

Chat Link or Prompt/Response:

Prompt: "What should I validate for resume uploads, and what resume information should be stored in the database?"

AI-Suggested Content:

The AI suggested validating that a file is present, limiting the maximum file size, and accepting the document formats required by the implementation. It also explained the purpose of storing metadata such as the user ID, original filename, internal stored filename, content type, file size, and upload time.

Validation:

I reviewed these fields and checks in the context of the feature. I used a 5 MB maximum size and PDF/DOCX support. I also verified that the original filename is useful for display and download while the generated internal filename prevents collisions in local storage.

Decision:

Accepted after review.

Reflection:

This helped me understand why validation should happen before writing a file and why the user-facing filename should be separated from the internal storage filename.
