Sprint 2 AI Usage Log
Course: SOEN 341 – Software Process
Project: CareerConnect – Job Search and Application Tracking Platform
Sprint: Sprint 2
Responsible Person: Bilal Qadir

Task 1: Understanding Sprint 2 Tasks and Responsibilities
Purpose of AI Use:
I used ChatGPT to better understand the Sprint 2 tasks assigned to me and to separate which parts were frontend and which parts were backend.

Chat Link or Prompt/Response:
Prompt: I asked questions such as which assigned task was frontend, which was backend, and what each task required before starting implementation.

AI-Suggested Content:
ChatGPT explained the purpose of the assigned Sprint 2 tasks and helped break them down into smaller implementation steps. This included Edit and Manage Job Postings, Search for Jobs, View Created Job Postings, and Application Status Updates.

Validation:
I checked the explanations against the GitHub issue descriptions and the Sprint 2 requirements before making changes.

Decision:
Used as guidance.

Reflection:
The AI helped me understand what each issue was asking for before I started coding and made it easier to plan the order of the work.

Task 2: Implementing Edit and Delete Job Posting Functionality
Purpose of AI Use:
I used ChatGPT to understand how the existing job posting backend was structured and where the edit and delete functionality should be added.

Chat Link or Prompt/Response:
Prompt: I asked how the update and delete endpoints should fit into the existing controller and service structure and how ownership of a job posting should be handled.

AI-Suggested Content:
ChatGPT explained the general controller and service flow for updating and deleting job

postings and pointed out that the owner of the posting should not be changed during an update.

Validation:
I reviewed the existing backend classes, compared the changes with the issue requirements, compiled the backend, and tested the endpoints.

Decision:
Used as guidance.

Reflection:
The AI was useful for helping me understand the existing backend structure and the expected behavior, especially around ownership checks.

Task 3: Implementing Search for Jobs Frontend
Purpose of AI Use:
I used ChatGPT to understand how the search page should work with the real job posting API instead of mock data.

Chat Link or Prompt/Response:
Prompt: I asked how to connect the Search for Jobs page to the existing backend API and how the keyword, location, and category filters should work.

AI-Suggested Content:
ChatGPT explained how to fetch the job postings from the backend, store them in the frontend, and apply the search and filter logic to the returned data.

Validation:
I reviewed the existing frontend structure, implemented the changes, tested the page in the browser, and checked that the jobs displayed were coming from the backend.

Decision:
Used as guidance.

Reflection:
The AI helped me understand how to replace the mock data with real API data and how to organize the filtering logic. I adjusted the implementation based on the existing project structure and reviewer feedback.

Task 4: Implementing View Created Job Postings Backend
Purpose of AI Use:
I used ChatGPT to understand how recruiters should retrieve only the job postings they created and how the logged-in user's identity should be used.

Chat Link or Prompt/Response:
Prompt: I asked how to use the authenticated user's session to retrieve their own job postings and how to add an endpoint for viewing applications to a specific posting.

AI-Suggested Content:
ChatGPT explained how the authenticated user's ID could be obtained from the session and passed to the service layer. It also helped explain how to verify that the recruiter owns the job posting before returning its applications.

Validation:
I reviewed the authentication code, implemented the endpoints, and tested them using an authenticated account and Postman. I tested both an empty applications list and a submitted application.

Decision:
Used as guidance.

Reflection:
The AI helped me understand how authentication and ownership checks should be connected to the feature. Most of the work involved fitting the new endpoints into the existing backend structure.

Task 5: Implementing Application Status Updates
Purpose of AI Use:
I used ChatGPT to clarify how the application status feature should be implemented based on the issue requirements.

Chat Link or Prompt/Response:
Prompt: I asked how the required statuses Applied, Interview, Offered, and Rejected should be represented and how the status update should be saved.

AI-Suggested Content:
ChatGPT suggested defining the statuses using an enum, setting new applications to Applied, and adding backend functionality to update and save the status of an existing application.

Validation:
I compared the implementation with the issue requirements, compiled the backend, and tested the full status flow using Postman. I confirmed that Applied, Interview, Offered, and Rejected were accepted, invalid values were rejected, and the final status was persisted.

Decision:
Used as guidance.

Reflection:
The AI helped me understand a cleaner way to represent the statuses and also helped identify an older Submitted status that no longer matched the Sprint 2 requirement.

Task 6: Troubleshooting Build and CI Errors
Purpose of AI Use:
I used ChatGPT to help interpret compiler errors and GitHub Actions failures after changing the application status field from a String to an enum.

Chat Link or Prompt/Response:
Prompt: I shared the Gradle and GitHub Actions error messages and asked what needed to be changed.

AI-Suggested Content:
ChatGPT identified that some existing tests were still using String values such as Submitted, Interview, and Offered. It explained that the tests needed to be updated to use the new ApplicationStatus enum.

Validation:
I updated the test files, ran ./gradlew build locally, and confirmed that the build passed before pushing the changes. The GitHub CI checks also passed afterward.

Decision:
Used as guidance.

Reflection:
This was one of the most useful parts of the AI assistance because it helped me quickly understand why the production code compiled but the CI build was still failing.

Task 7: Resolving Git and Pull Request Conflicts
Purpose of AI Use:
I used ChatGPT to understand how to resolve branch conflicts and clean up the Search for Jobs pull request without losing my work.

Chat Link or Prompt/Response:
Prompt: I shared the Git conflict messages and asked how to safely rebuild the branch on top of the latest main branch.

AI-Suggested Content:
ChatGPT explained how to create a backup branch, reset the feature branch to the latest main branch, cherry-pick the relevant commits, resolve file conflicts, and safely force-push using --force-with-lease.

Validation:
I checked the resulting commit history, confirmed that the pull request had no remaining conflicts, and waited for the Gradle checks to pass before merging.

Decision:
Used as guidance.

Reflection:
The AI helped me understand the Git conflict resolution process instead of randomly choosing conflict options. This was especially useful because the branch history had become messy after earlier merges.
